Designing and Implementing a Web Application with Spring

In this tutorial you'll learn to use Spring to create production-strength web applications.

Spring and the Web

The web has become a core part of our lives, from shopping to finding the closest ATM. Web applications, server software sending HTML over HTTP, implement the web.

Spring helps you build web applications that scale from a small internal application to those serving millions of users and thousands of concurrent requests.

Whether you are beginning the construction of a web application using Spring, or are just curious on what a Spring backed web application looks like, you've come to the right place.

What you'll build

Yummy Noodle Bar is going global. It wants to build an interactive web application to provide customers with the latest Yummky Noodle Menu and allow them to place orders and monitor the status of their order as it is being prepared.

You will extend Yummy Noodle Bar's existing application by adding an web components that will allow viewing the menu, creating and viewing the status of orders.
